
Problem A. Formulate this as a linear program (hint: we did, in class, already) and use the `LinearOptimization` command in Mathematica (and not other software) to solve. Translate the Mathematica answer to a practical, common language answer and check if the answer makes sense. Include the Mathematica code and answer in what you turn in.

An investor has money-making activities A and B available at the beginning of each of the next 5 years (call them years 1 to 5).

Each dollar invested in A at the beginning of 1 year returns \$1.40 (a profit of \$0.40) 2 years later (in time for immediate reinvestment).

Each dollar invested in B at the beginning of 1 year returns \$1.70 3 years later.

In addition, money-making activities C and D will each be available at one time in the future.

Each dollar investment in C at the beginning of year 2 returns \$1.90 at the end of year 5.

Each dollar invested in D at the beginning of year 5 returns \$1.30 at the end of year 5.

The investor begins with \$50,000 and wishes to know which investment plan maximizes the amount of money that can be accumulated by the beginning of year 6. How?

Problem B. Textbook, Section 1.9, Exercise 4.
